

Chapter 1

Introduction

1.1 Background to this Study

Human motion capture systems are often very costly and confine the capture area to a certain confined space. These limitations prevent us from understanding bipedal motion in complex environments, knowledge that proves to be critical in the development of functional humanoid robotics. Examples of such systems can be seen in [1] where 8 cameras and stereo vision was used to recreate a 3D model of a walking person and in [2] where 10 Vicon cameras and a full body marked suit was used for the same objective.

A popular approach taken to overcome the spatial limitations inherent in camera based systems is the use of body mounted sensor networks. A commercial sensor suit developed by XSens and demonstrated in [3] can accurately recreate a 3D model of human motion using inertial sensors and data fusion. Similar work completed by Seel et al. [4] further proves the accuracy of such systems. Although the mentioned systems overcome the stated limitations; they do so at increased complexity and cost.

Figure 1.1: Left: Vicon motion capture system tracking the human gait (from [3]) Right: The Xsens MVN motion capture suit (from [5])

Recent work [6] completed by the Mechatronics Lab at the University of Cape Town showed data capture with both subject-borne cameras and sensors can be used to better understand unconstrained movement in a natural environment. This was based on research completed by Stocks [7] completed at the same laboratory. The presented work showed the successful kinematic modelling of a cheetah (*Acinonyx jubatus*) tail whilst running freely. The importance of understanding motion in the natural world is outlined in [8] and is the cornerstone of biomimicry as defined by [9].

1.2 Objectives of this Study

Depth imagery in the field of human motion capture has been extensively reviewed in [10], where the lack of data from complex movements in different environments is listed as a challenge. This reaffirms the difficulty stated in the previous section. Solely relying on motion sensors to understand the gait has been reviewed by [11]. Although this approach was found to be accurate for external environments it has limitation with respect to cost and sensor disturbance. From these reviews it is clear that a middle ground must exist that can combine the strengths of the approaches to provide a holistic solution.

This research project aims to show that subject-borne sensors, primarily a combination of cameras and IMUs, can provide researchers in the field of health sciences, biomechanics and biomimicry with extensive datasets to better understand and model the bipedal motion of humans. It builds on the foundational work presented by Stocks and Patel [7] and envisions to implement a similar system to track data points on the lower limbs of a runner.

1.3 Scope and Limitations

The scope of this research is to model and estimate the human lower limbs during a flat ground steady state run. The motion will be estimated by determining the different joint angles as well as the motion of the runner w.r.t. the inertial frame. Joint angles are a popular method of quantization and the availability of rich dataset allow comparative analysis on the final findings of this work. This is the first logical step in the iterative design process to eventually understand movement in complex environments using wearable motion capture systems.

It should be noted that the research presented herein does not seek to push the boundaries of modern sensor technology, nor does it wish to re-imagine understood and accepted models of natural phenomena. Instead, a methodology is proposed that brings together systems from exciting disciplines of research such that richer datasets can be generated and studied. This research therefore serves as a proof of concept for a novel wearable motion capture technology.

1.4 Plan of Development

The following chapter contains an extensive literature review where various methods of modelling and verifying the human gait has been discussed. There are also sections dedicated to subject borne data capture, computer vision, inertial measurement units (motion sensors), humanoid robotics and mathematical modelling.

This is followed by a chapter titled methodology that presents the the planning and ideation of the thesis. It serves as a link between the theoretical work presented in the literature review and the engineering approach and application detailed in the chapters that follow it. It lays out a plan and shows how engineering specifications were generated from a generally defined problem.

The final three chapters that make up the body of this report are titled "Designing the Data Capture System", "Processing the Captured Data" and "Data Fusion and State Estimation" in order of appearance. True to their title they present the process followed to complete the major milestones of the project.

In closing a chapter is dedicated to presenting and discussing the results obtained, followed by the final chapter that draws conclusions from the presented work and makes recommendations on future work. The following flow digram summarizes the progression of this report.

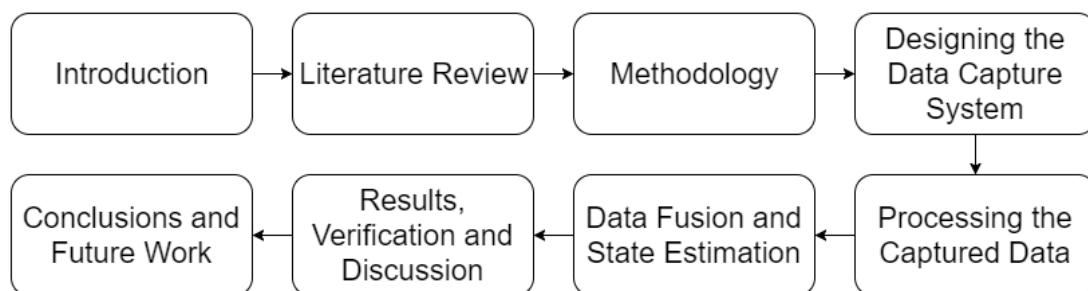

Figure 1.2: Flow chart outlining the report structure

Chapter 2

Literature Review

This section reviews various academic sources related to the methodology proposed.

2.1 Introduction

This research project brings together various disciplines of research. By combining techniques from computer vision, sensors and data fusion we can design and develop new way of capturing human gait data.

2.2 Human Motion and Gait

The human gait is well understood and has been studied in detail as it is a fundamental part of human mobility. It is one of the first skills developed in infancy and its importance for healthy development, as outlined by Adolph et al. [12], cannot be understated. Walking and running are also critical factors in transportation and geographical movement of people and goods in developing countries where public transport is underdeveloped and private transport not within the means of the populous. Finally walking and running as exercise has proven benefits as shown in [13] (general health) and [14] (mental health).

There is thus clear evidence that the human gait has earned its right as a field of study in academia.

2.3 Computer Vision

While the previous section answers "why" understanding the human gait is important, the following sections will explain fields that contribute to the question of "how" the gait is studied.

Computer vision is a field borne from image processing and artificial intelligence that seeks to replicate the ability of the human visual system.

2.3.1 Computer Vision in robotics

2.3.2 New Perspectives from Animal Borne Cameras

In large this researched project was inspired by work done in the Mechatronics Lab at the University of Cape Town. In 2017, Patel et al. [6] showed that using animal borne cameras and motion sensors, the tail kinematics of the cheetah (*Acinonyx Jubatus*) could be tracked. Patel's work was partly inspired by Kane et al. [15] where falcon (*Falco Peregrinus*) borne cameras were used to better understand airborne pursuit of prey.

Further work completed by Pearson et al. [16] showed that cameras mounted to dolphins (*Lagenorhynchus obscurus*) could provide insight into the their movement, social and foraging strategies. These examples show the promise that animal borne

2.3.3 Human Motion Analysis Using Computer Vision

2.4 Inertial Measurement Units

IMU's are a staple of electrical engineering as applied to dynamic systems. These sensors give us insight as to how an object is moving in space by providing data relating to orientation and acceleration of said system. These data points are created by electronically interpreting signals generated by micro-electromechanical system (MEMS). Modern smartphones have built in IMU's that are not only accurate [17], but also easy to interface with due to the open source nature of the Android operating system [18].

Generally IMUs contain the following subsystems:

- Accelerometer
- Gyroscope
- Magnetometer
- Barometer
- Temperature

Accelerometers provide linear acceleration data; these accelerations may be constant (eg. gravity) or changing (eg. relative motion). In smartphones they are usually based on MEMS that use

2.6 Observing Natural Solutions for Robotic Shortcomings

Naturally the question arises: why would we want to better understand the dynamics of animals? A persistent problem in the field of modern robotics is that of mobility; robots struggle to navigate real world surfaces and obstacles. Work by Patel et al. [19] shows how we can look towards nature for inspiration to solve this mobility problem.

This follows the central philosophy of bio-inspired robotics as defined by

As demonstrated by various prototype robots built by Boston Dynamics bipedal robots are severely limited in manoeuvrability when compared to

Chapter 3

Methodology

To ensure the success of this project a basic plan of action was created. The following diagram shows the critical phases of the project.

Figure 3.1: Diagram showing the progression and dependence of the major stages of this project

Due to the availability of equipment, financial limitations and time

3.1 System Design

This section is dedicated to defining and understanding the specifications of the data capture system. The system will consist of 4 cameras and an IMU mounted to the torso of the subject. the cameras will record the legs of the subject while the IMU will log inertial data from the body of the subject.

Due to the availability of equipment provided by the Mechatronics Lab the following equipment was chosen as the main components to use in the system:

Item	Selected Equipment	From
Camera	4 GoPro Hero Session Cameras	[20]
IMU	1 Sony Xperia Z3 Compact	[21]
Chest Mount	1 Action Mount Chest Mount	[22]

Table 3.1: The main components used.

The specifications of this data capture system has been defined as:

- Stereo housing to hold the cameras.
- Chest mount to hold the cameras and IMU.
-
-

3.2 Modelling the Lower Limbs

3.3 Experimental Details

The data was captured during a short

3.4 Limitations

Chapter 4

Designing the Data Capture System

To obtain data for the Extended Kalman Filter, a data-capture system needed to be designed. Since the data sources have been identified as multiple video sources and a 9-DOF IMU.

Chapter 5

Processing the Captured Data

This chapter is dedicated to the complex process of extracting critical data from the video files. The following digram shows the process of converting a data heavy video file to a more lightweight .csv (Comma Separated Values) file.

Figure 5.1: Diagram showing the progression and dependence of the major stages of video processing in the project

5.1 Obtaining Video Data

Using the chest mounted cameras detailed in the previous chapter we can generate raw video data. The GPHS cameras can be configured to record at different frame rates and resolutions.

5.2 Synchronizing Video Sources

A typical problem faced when working with different sources of data is that of synchronization. Since this project used 4 different cameras, synchronizing the video sources are critical

to generate accurate stereo vision data.

The problem of synchronization was overcome by using an audio cue to align the video data post capturing. With all systems recording, a simple hand clap can serve as a spiking audio input easily identified in the audio track of the video streams. The frame associated with this audio spike can be identified using SVP (Sony Vegas Pro) video editing software as shown in the figure below.

Figure 5.2: Figure showing the user interface of SVP video editing software

The red track in the above figure shows the recorded audio stream while the corresponding frames are displayed in the blue track above that. The cursor is aligned with the audio spike caused by the clap with the corresponding frame number displayed below the playback controls.

This method was repeated for every video stream such that a common starting point was generated.

5.3 Cutting Critical Video Data

With the video data synchronized the next step was to generate a subset of video demonstrating a transient period and steady state period of running. From accelerometer readings we can easily determine the gait cycle period of our subject; that is the amount of time taken between the same foot impacting the ground. These impacts are visible as spikes as seen in the accelerometer data.

5.4 Undistorting the Video Data

To generate accurate distances using stereo vision the video frames need to be undistorted.

Distortion of the frames is a result of the

[25]

using work from [26]

Chapter 6

Data Fusion and State Estimation

This chapter is dedicated to explaining the mathematical methods and models used to fuse data generated by the cameras and IMU.

State	Description
x_{body}	x Position of body w.r.t. the global frame
y_{body}	y Position of body w.r.t. the global frame
z_{body}	z Position of body w.r.t. the global frame
θ_{body}	Pitch of body w.r.t. the global frame
ϕ_{body}	Roll of body w.r.t. the global frame
ψ_{body}	Yaw of body w.r.t. the global frame
θ_{LH}	Pitch of left thigh w.r.t. left hip
ψ_{LH}	Yaw of left thigh w.r.t. left hip
θ_{LK}	Pitch of left calf w.r.t. left knee
θ_{LA}	Pitch of left foot w.r.t. left ankle
θ_{RH}	Pitch of right thigh w.r.t. right hip
ψ_{RH}	Yaw of right thigh w.r.t. right hip
θ_{RK}	Pitch of the right calf w.r.t. right knee
θ_{RA}	Pitch of the right foot w.r.t. the right ankle

Table 6.1: Table showing the different states of the model to be determined by the kalman filter.

we will use derivatives

all the derivatives

$$q = [x_{body} \ y_{body} \ z_{body} \ \theta_{body} \ \phi_{body} \ \psi_{body} \ \theta_{LH} \ \psi_{LH} \ \theta_{LK} \ \theta_{LA} \ \theta_{RH} \ \psi_{RH} \ \theta_{RK} \ \theta_{RA}]$$

all the states totalling 42 states

$$Q = [q \ \dot{q} \ \ddot{q}]$$

all 42 and their equations

positional

$$\begin{aligned}\ddot{x}_{k+1} &= \ddot{x}_k + \sigma_{\ddot{x}}^2 \\ \dot{x}_{k+1} &= \dot{x}_k + \ddot{x}_k T + \sigma_{\dot{x}}^2 \\ x_{k+1} &= x_k + \dot{x}_k T + \sigma_x^2\end{aligned}$$

angular

$$\begin{aligned}\ddot{\theta}_{k+1} &= \ddot{\theta}_k + \sigma_{\ddot{\theta}}^2 \\ \dot{\theta}_{k+1} &= \dot{\theta}_k + \ddot{\theta}_k T + \sigma_{\dot{\theta}}^2 \\ \theta_{k+1} &= \theta_k + \dot{\theta}_k T + \sigma_{\theta}^2\end{aligned}$$

since all states are either positional(body) or angular(body and limbs) matrices: rotational matrices

$$\begin{aligned}\text{x axis} & \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \phi & -\sin \phi \\ 0 & \sin \phi & \cos \phi \end{bmatrix} \\ \text{y axis} & \begin{bmatrix} \cos \theta & 0 & \sin \theta \\ 0 & 1 & 0 \\ -\sin \theta & 0 & \cos \theta \end{bmatrix} \\ \text{z axis} & \begin{bmatrix} \cos \psi & -\sin \psi & 0 \\ \sin \psi & \cos \psi & 0 \\ 0 & 0 & 1 \end{bmatrix}\end{aligned}$$
